

Deploying Uni-Dash to the edge

Edge deployment from commit to container

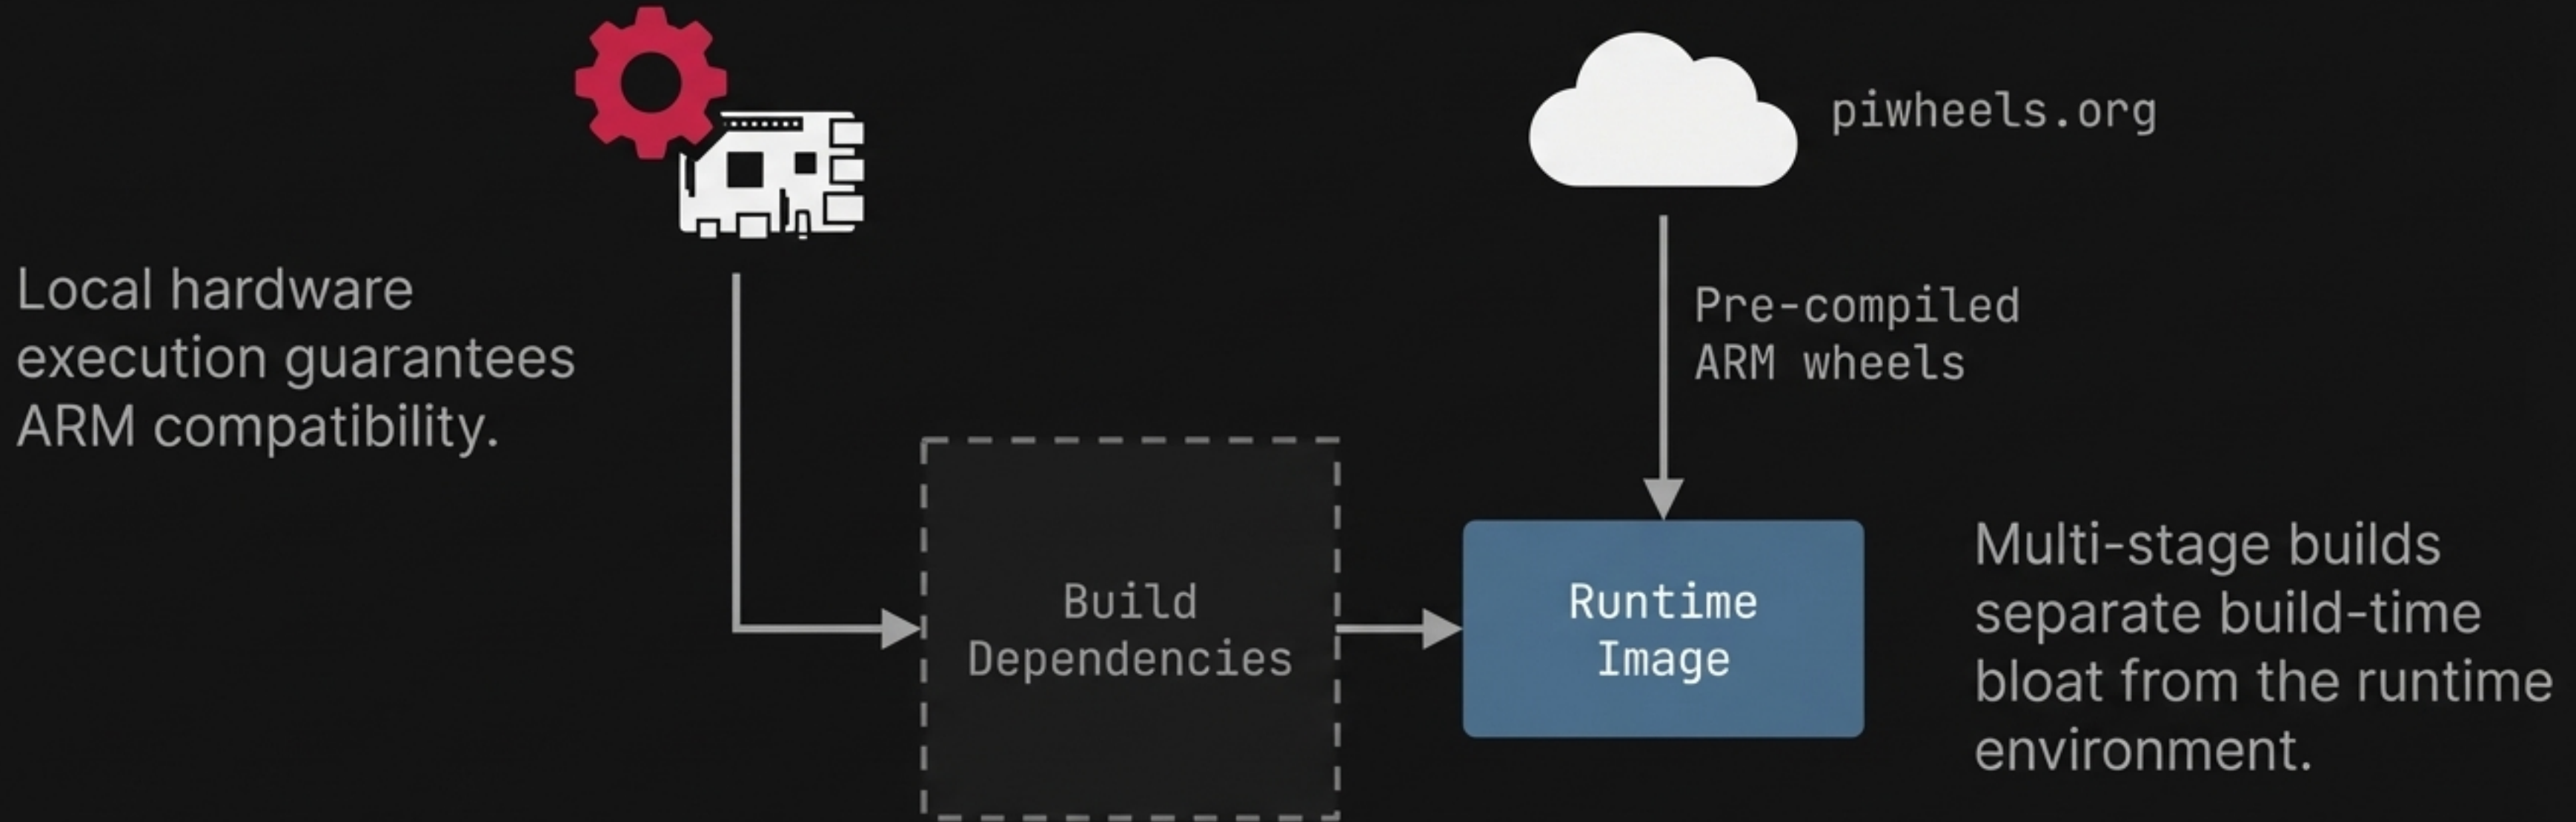

Every push to main triggers a self-hosted GitHub runner on the Raspberry Pi which builds and redeploys the backend container.

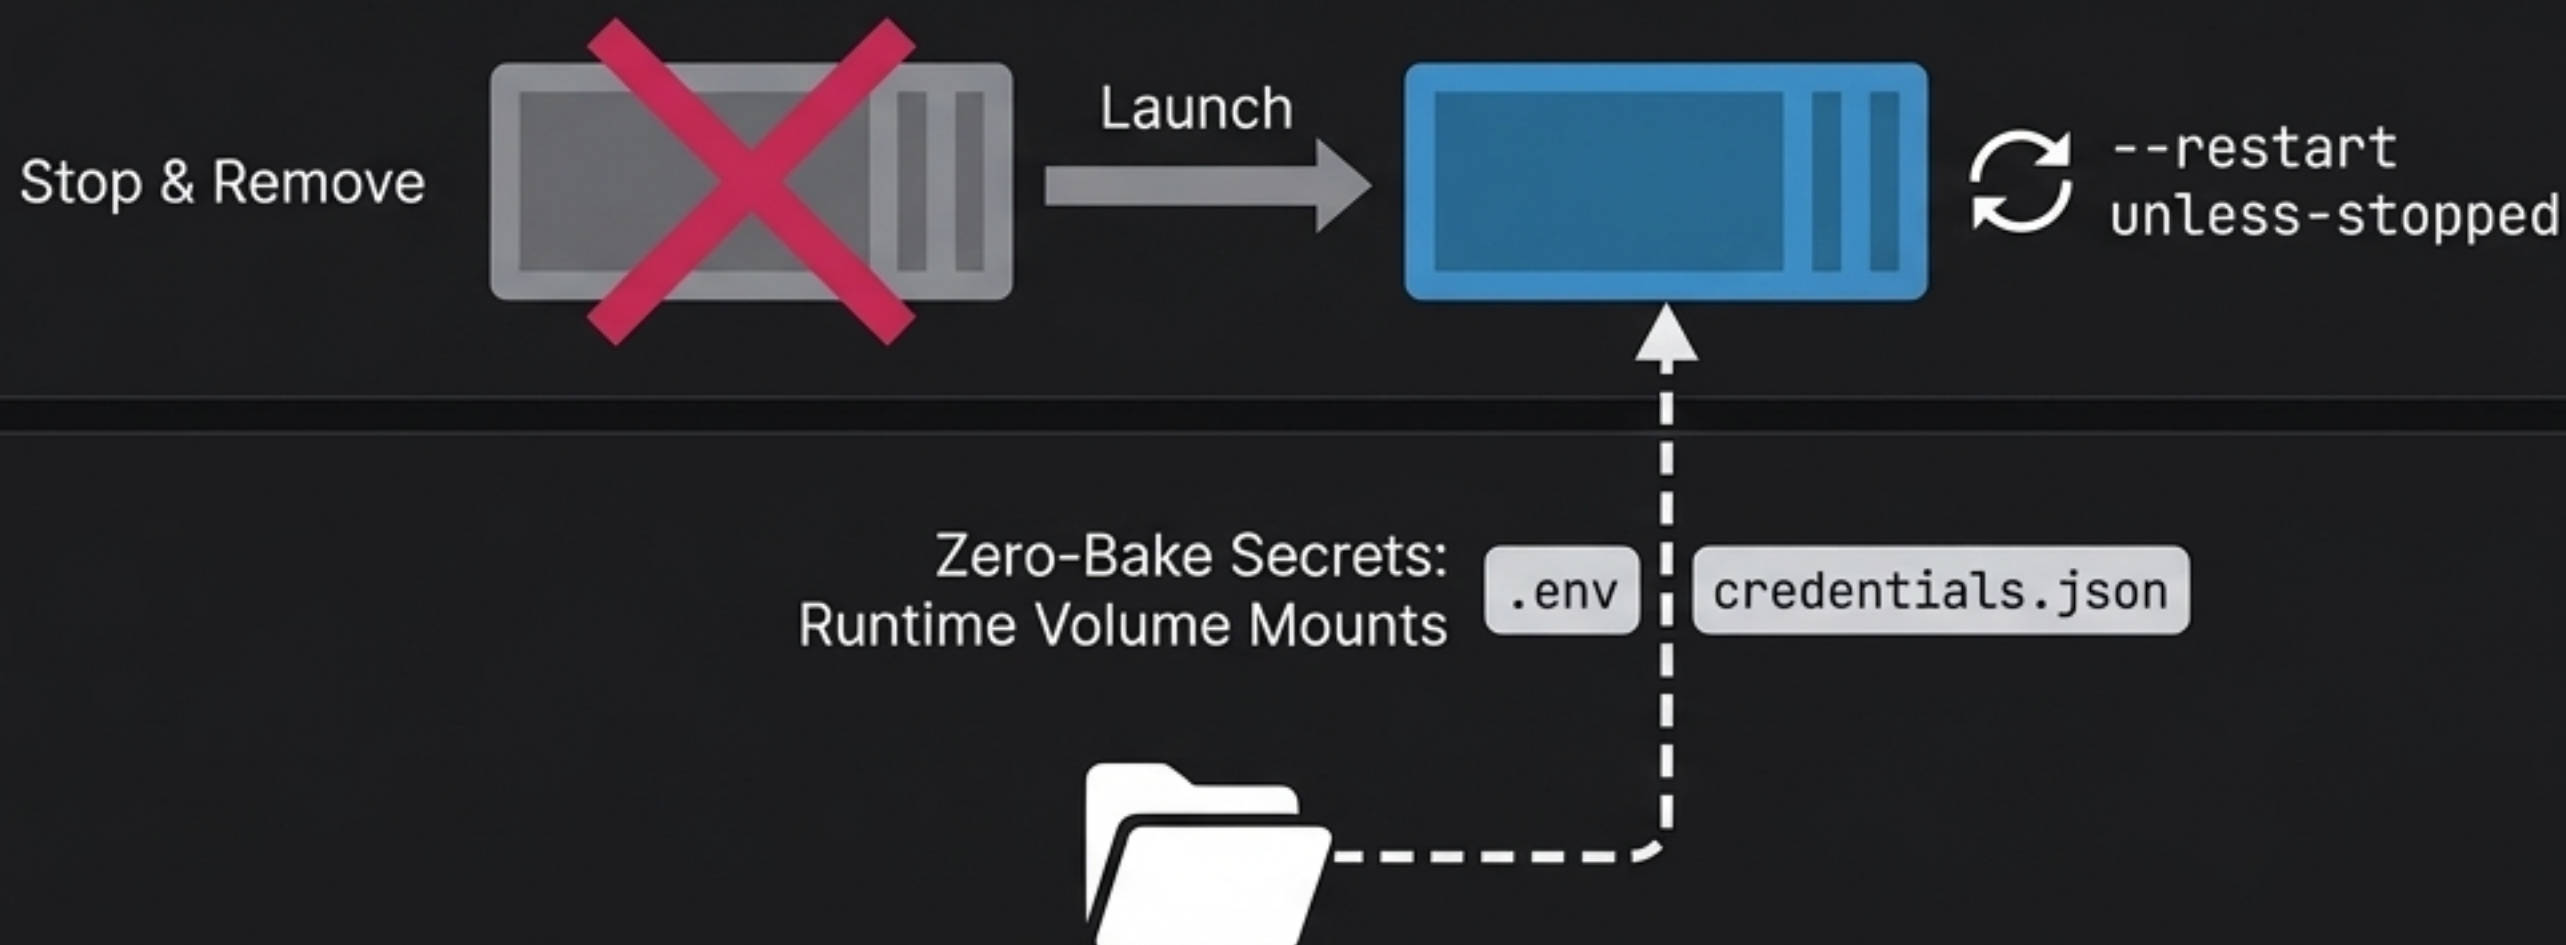

Reproducible environment.

Zero credential leakage into the repository.

Building the lean ARM image

Zero-downtime atomic container swaps

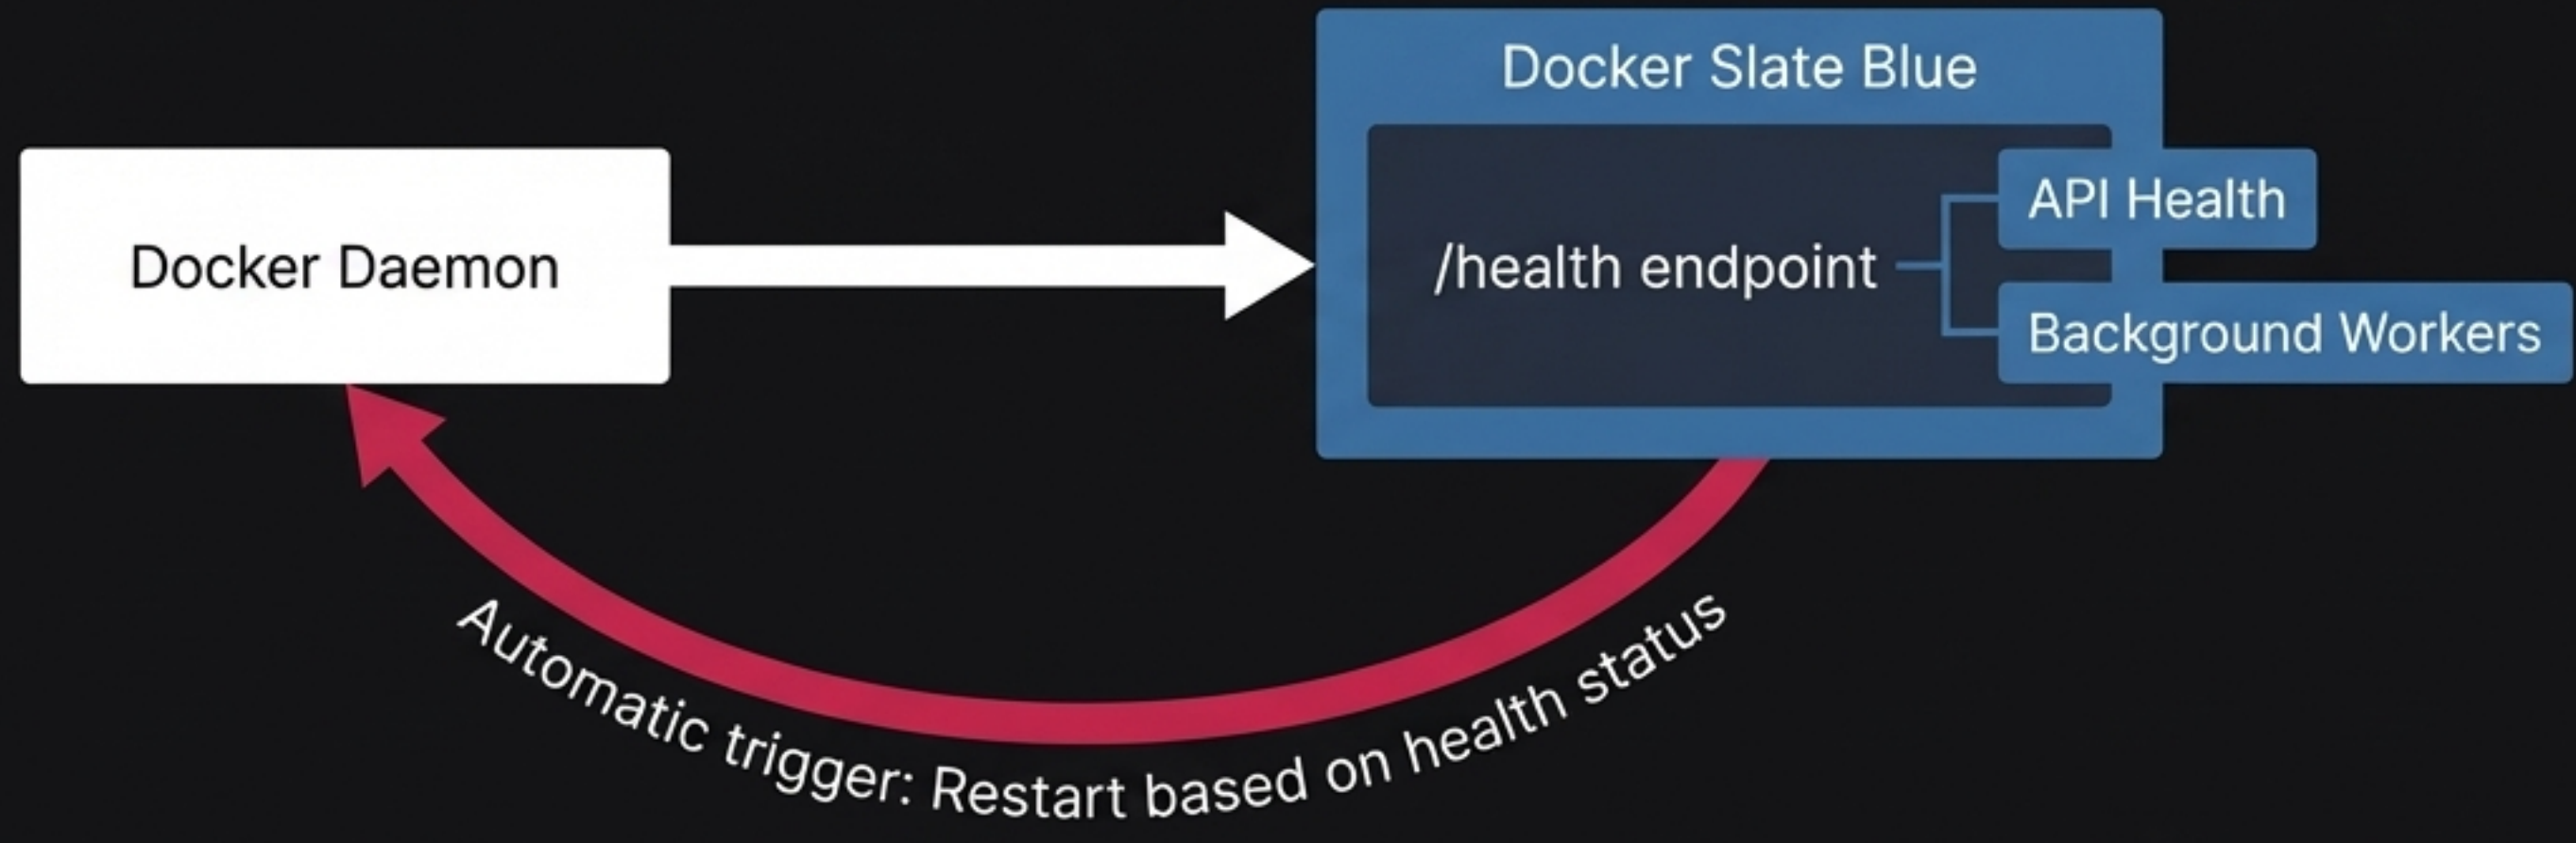

Atomic replacement guarantees a clean state.

Host-level volume mounting prevents secrets from entering image layers.

Configured with `--restart unless-stopped` for reboot recovery.

Automated self-healing and runtime resilience

- Specialised /health endpoint monitors core API and worker behaviour.
- Docker daemon acts as an autonomous watchdog.
- Self-healing architecture requires zero manual intervention.
